## Summary

In this study, 38 fish in four species of Shapour River and Seyyed Hossein Spring were caught in 2016, including: *Alburnus mossulensis*(kuli), *Cyprinion macrostomum*(Lotak), *Capoeta barroisi persica*(Siah mahi) and *Garra rufa* (Doctor fish) and they were studied internal helminthes parasites. Totally, four parasites were isolated and recognized, including: two Digenea (*Allocreadium* sp. and *Haplorchis* sp.), one Cectoda (*Bothriocephalus* sp.), one Nematoda (*Rhabdochona* sp.) The results showed that the highest percent of parasitic infection was for *Allocreadium* sp. and the least amount was reported for *Haplorchis* sp. Moreover, kuli and Siah mahi had the highest and lowest percent of parasitic infection, respectively. There wasn't any meaningful relationship between fish species and frequency of infection ( $P>0/05$ ). However significant relationship was detected between sex and frequency of infection ( $P\leq 0/05$ ).

**Keywords:** *Internal Helminthes, Seyyed Hossein Spring, Shapour River, Cyprinid Fish, Kazerun*

## Introduction

Parasites in fish have been a great concern since they often produce disease conditions in fish which will lead to reduced growth, increase in the fishes' susceptibility to other diseases as well as fish loss. Parasites may be the cause of growth reduction, fatality, delayed puberty or infertility in the fish and they are often the reason for microbial, viral and fungal diseases. In some cases, parasites are the cause of high fatality of the fish (Abbasi, 2003). Studies on parasites of Iranian fish species date back to 1949, when Bychowsky reported three Dactylogyrus species and one Ancyrocephalus on the gills of fishes in Karkheh River. Since then other researchers reported more parasites from Iranian freshwater fish. Iranian freshwater fish habitats can be categorized according to three different faunal regions: the Ponto-Caspian Territory of northern Iran, as a part of the Palaearctic zone; southeastern Iran that is greatly influenced by the Indian faunal region, and southwestern Iran that falls within the Mesopotamian intermediate faunal region (Figure 1). Various studies have been conducted with respect to the study of parasite infection of freshwater fish in Mesopotamian and the other areas in Iran (Pazooki and Masoumian, 2012). The most important studies in this area are as: Mortezaei et al. (2000) on parasite infection of freshwater fish in Hoorolazim and Shadegan Suns, Farahnak et al. (2002) in Khuzestan Basins, Abbasi et al. (2003) and Barzegar et al. (2004) studying parasites of the Behesht Abad River, and Raissy et al. (2009) in identifying the parasites of 3 kinds of

Figure 1. Iranian freshwater fishes' fauna regions; 1: Ponto-Caspian Territory, 2: Mesopotamian Intermediate Fauna Region, 3: Indian Fauna Region (Pazooki and Masoumian,2012)

*Barbus capito* in Kiar and Behesht Abad Rivers in Chahar Mahal and Bakhtiari Basins. The importance of the identification of the parasites is that, on one hand, a large group of animals are studied and different kinds of parasites as infecting a host could be recognized and on the other hand, they can infect the farmed fish, as well.

Shapour River originates from Ranjan Spring and connects Sasan Spring in Tange Chowgan area and flows toward Bushehr. In Bushehr, this river touches Dalaki River and then finally joins Persian Gulf called Hilla River. Shapour River is very vital in Kazerun, providing this area's water which is consumed for agriculture. Seyyed Hossein Spring is located twenty-three kilometers away in Kazerun Road. The fish species in this river have nutritional value and are caught recreationally or for eating, thus recognizing their parasite gamut is very essential and this study has been carried out accordingly. This study, therefore, aimed at detecting the occurrence of parasites in fish in Shapour River and Seyyed Hossein Spring, Kazerun Province, with regard to the importance of native fish population in the river.

### Material and Methods

Early morning, a total of 38 fish including kuli, Lotak, Siah mahi and Doctor fish were caught using gillnet and Sachuk Net and they were transferred alive to the Laboratory of Parasitology, Faculty of Veterinary Medicine, Islamic Azad University, Kazerun and were kept in the aquarium. The fish were anaesthetized using 170 ppm powder of *Eugenia* sp. (Rastiannasab et al., 2014). Immediately after anesthesia, they were identified based on recognition keys of Berg (1964), and Coad (1992). The methods and techniques used for collection, relaxation, fixation, staining and mounting of helminthes are basically those described by Hanek and Fernando (1972) and Roberts (2001). Fish were dissected for internal examination and studied for cysts and endoparasites in the muscles and visceral organs. Abdominal cavity of each fish was washed with a 0.6% saline solution for abdominal parasites.

Then the gastrointestinal tract was dissected for examination. Intestine cut open longitudinally, the contents were washed was removed, placed in a petri dish, and examined for helminthes using an Olympus SZ Series 51stereomicroscope. Nematodes were washed in saline (0.6%-0.8%) and fixed in hot 76% ethylalcohol and cleared in Glycerin or in hot lactophenol. For permanent preservation mounted on azocarmin stains. All Nematodes were identified. Using descriptions identification keys Yamaguti (1961), Gussev (1985) and Moravec (1994). Acanthocephalans were isolated from dissected Fish hosts then fixed in 70% ethanol then stained in Mayer's carmine or azocarmin. After staining, dehydrated in alcohol series, for clearing were placed in xylol and finally mounted in Canada balsam. Then the parasite was identified, according to morphological characteristics and followed the key to the families and subfamilies of Acanthocephala (Amin, 1987). All isolated nematodes and acanthocephalans specimens in each individual fish were identified and counted. In this study, the data were processed using SPSS 18 software. The frequency and Pearson Chi-Square test were used to compare the infection among different kinds of fish species and the infectious frequency and between sex and the infectious frequency.

## **Results**

Totally, four internal parasites were isolated from the intestine , gall bladder ana air sac of four fish species caught in the river(Table 1). They were identified for their genus, including one Digene (*Haplorchis* sp., frequency 6.5 % and *Allocreadium* sp. frequency 48.8 %), one cestode (*Bothriocephalus* sp., frequency 12.9% ), and one Nematode (*Rhabdochona* sp., frequency 32.3 %). Therefore as the results showed, *Allocreadium* sp. demonstrated the highest and *Haplorchis* sp. presented the lowest frequencies(**Diagram 2**). The highest infection was detected in kuli with 40 % frequency and the least infection was observed in Siah mahi with 10 percent frequency(**Diagram 1**). The average intensity of infection in Siah mahi with  $0.33 \pm 0.48$ , Lotak with  $0.4 \pm 0.54$ , kuli with  $0.8 \pm 0.42$  and Doctor fish with  $0.6 (\pm 0.54)$  was calculated (**Diagram 3**). Using Pearson Chi-Square test showed that no meaningful relationship was detected between fish species and frequency of infection( $P > 0/05$ ). However there was significant relationship between sex and frequency of infection ( $P \leq 0/05$ ).

**Table 1.** Isolated internal helminthes of the fish in Shapour River and Seyyed Hossein Spring based on the infected organ and its host

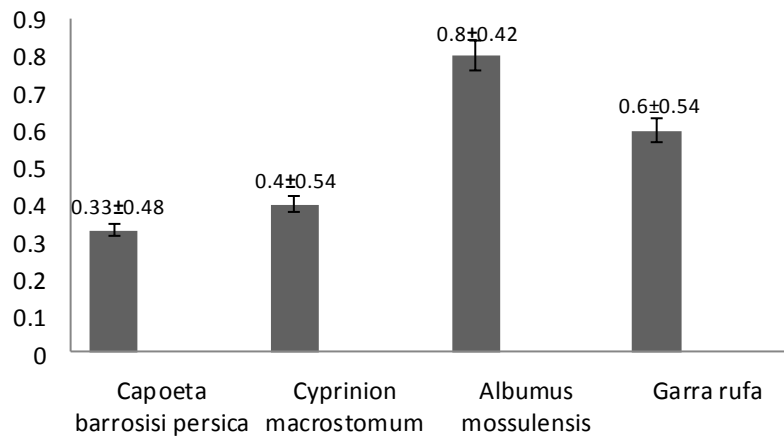

| Parasite                   | Infected Organ             | Fish Species                    |
|----------------------------|----------------------------|---------------------------------|
| <i>Allocreadium sp.</i>    | Intestine and Gall Bladder | <i>Capoeta barroisi persica</i> |
| <i>Haplorchis sp.</i>      | Air sac                    |                                 |
| <i>Rhabdochona sp.</i>     | Intestine                  | <i>Albus mossulensis</i>        |
| <i>Allocreadium sp.</i>    |                            |                                 |
| <i>Bothriocephalus sp.</i> |                            |                                 |
| <i>Rhabdochona sp.</i>     | Intestine and Gall Bladder | <i>Cyprinion macrostomum</i>    |
| <i>Allocreadium sp.</i>    |                            |                                 |
| <i>Haplorchis sp.</i>      | Air sac                    | <i>Garra rufa</i>               |
| <i>Rhabdochona sp.</i>     | Intestine                  |                                 |
| <i>Allocreadium sp.</i>    |                            |                                 |

## Discussion

Throughout the time, a balanced condition would be developed among parasites and the host in natural environments, but in high fish density in cultural and environmental stressful conditions, parasites would make many problems for the reproduction (Bush et al., 2001) and despite parasitic infection of the fish, no clinical signs of the disease were observed which confirm the balance of parasite and the host in natural environments. Aquaculture development in today's world and economy of various countries has an important role in the human food supply.

One of the main conditions for suitable production is fish health and prevents disease among them, including parasitic diseases that affect the behavior of fish growth and reduce marketable yields. So recognizing these factors is essential to eliminate or minimize these problems (Seyed Mortezaei et al., 2000). Among the large number of parasites recorded from different parts of the world, research on parasites in Iranian freshwater fish is very new. Many fish parasites from different parts of the country were expected, but only 247 species have been reported so far. The parasites, recorded from the Mesopotamian part of Iran, some new hosts were reported as well as some endemic and introduced species (Pazooki and Masoumian, 2012). During this study two Digenea, one Cestod, one Nematod were identified. *Allocreadium isoporum* has already been reported from the intestine of *Alburnoides bipunctatus* from the Gorgan Roud River (Jalali, 1998), *Leuciscus cephalus* from the Zayandeh Roud River (Williams et al., 1980) and *Allocreadium pseudaspis*, *barbulus barbulus* and *Capoeta damascina* (Raissy et al., 2011). This parasite may be pathogenic in cultured fishes (Woo, 2006). This study revealed that kuli, Lotak and Doctor fish, from Shapour River and Seyyed Hossein Spring were infected with *Rhabdochona* sp. which was originally described by Moravec (1994) from the intestine of *Varocorhinus capoeta* in freshwater in Azerbaijan. This parasite lives in intestine, liver, abdominal area, muscles and blood vessels and also was isolated by from *pike* and *Barbus spp.* (Eslami et al., 1972), *Chalcalburnus chalcoides* (Pazooki and Masoumain, 1999), *Silurus glanis* (Jalali, 1998), *Capoeta capoeta* from Freshwater Fishes of Northwest Iran (Pazooki et al., 2007) and was reported by Pazooki and Aghlmandi (2002), Syed Mortezaei et al. (2007) (*R. denudata* and *R. fortunatowi*) from Khuzestan, Raissy et al. (2011) (*Rhabdochona denudata*) from Armand River, Mohajeri et al. (2017) from Dalaki River. Among cestodes *Bothriocephalus* sp. was isolated from kuli, which this parasite has not been reported from mentioned fish until now. This cestode is the most dangerous warm water fish parasites that severe infection with the parasite causes intestinal obstruction or perforation it. Fortunately, the chemical treatment of contaminated fish can be fought to the cestode. However, due to the large Volume of water in the dam and the use of water as a source of drinking water can't action this affair (Jalali 1998). Also *Bothriocephalus* sp. was reported in many freshwater source such as: Mokhayer, 1981 from Sefid-Rood River; Masoumian et al. (2002); Raissy et al. (2011) from Armand River and Hosseinifard (2011) in Alborz dam. *Haplorchis* sp. was another internal parasite which isolated from air sac of Lotak and *Siah mahi*. The fish can be infected as the second host and this cycle is completed at the time that the fish are eaten by the final host including rats, penguins, birds and mammals and they become mature. Some human infections have also been reported by this parasite. For the first time, this parasite was detected in Asia (Chen, 1942) and later, it was reported in Mexico, Australia, Croatia and Turkey (Evans and Yildiz, 2005; Scholz and Salgado-Maldonado, 2000; Gjurcevic et al., 2007; Lester, 2001). Mood et al. (2010) identified this parasite in some imported aquarium fish. Recently Alamdari et al. (2017) reported it in the gill of Lotak and *Siah mahi* from Shapour River and Seyyed Hossein Spring.

### **Conclusion**

The results showed that varieties of nematodes, ceatodes and trematodes were distributed in different ecosystems and climates, as well as in zoogeographic features of native fishes. It would be interesting to consider

parasites may survive in different climates. Between fish Kuli showed the highest percentage of infection whereas Lotak had the lowest infection frequency. Also *Haplorchis* sp. was reported for the first time from air sac of fresh water fish.
